Reason for this Guide

This guide was created by the Washington State Department of Transportation (WSDOT) to promote good practice and uniformity in techniques being used for traffic counting and the estimation of Annual Average Daily Traffic (AADT) figures from short duration count data. It is an informational guide only, and does not constitute a specification or a statement of required practice. The intent is to encourage high standards and uniform practices among traffic counting programs within the State of Washington so that an accurate representation of traffic on our public roadways is available to all interested parties.

The Need for Good Data

The demand for accurate information concerning our transportation systems is increasing every day. Our state and local legislative bodies require more precise and thorough analyses in order to understand the increasingly complex systems they must guide. They also require sound planning options from which to choose. Analysis and planning begin with the collection of data, and their quality depends on the accuracy and completeness of that data.

Governmental personnel responsible for monitoring, maintaining and enhancing the performance of public roadways also require thorough and accurate data. Good data is needed for making a myriad of decisions in the design phase of construction projects, including what pavement depth and type are to be used, how many lanes will need to be constructed, what type of traffic control device(s) will be most effective, et cetera. The proper administration of construction and maintenance programs is also dependent on the availability of complete and accurate data, which is used in part to schedule the implementation of these programs so that worker and public safety is ensured. Furthermore, good data is required for monitoring the physical state of pavement and bridge decks, congestion, and other aspects of roadway condition and performance.

In addition, private interests and research organizations often request traffic information. Traffic data and analyses can be an important component of business decisions and research efforts.

Data collected by state and local governments is also requested by The Federal Highway Administration (FHWA). The data is used in the administration of the Federal-aid Highway Program, which distributes federal funds to the states for the construction and improvement of public roadways. In addition, the data is used in the preparation of the Secretary of Transportation's Report to the United States Congress entitled *The Status of the Nation's Highways, Bridges and Transit: Condition and Performance*. This report is the basis for many decisions made concerning federal highway program design and funds allocation.

There are many other demands for data, and more are coming in the foreseeable future. It is outside the scope of this document to address all of these, but simply to note that data is becoming more important with each passing day. We are indeed in an information age.

The Scope of This Guide

This guide provides a general overview of traffic counting programs, as well as a more detailed discussion of suggested practice in relation to short duration traffic count field and office techniques. Short duration counts are those that are conducted over a relatively limited period of time, usually one week or less. In addressing such counts, focus is placed on those performed with the primary intent of developing AADTs in order to fulfill federal reporting requirements and help meet point-specific and area-wide traffic information needs. Special purpose counts, such as traffic signal warrant studies and counts for intersection design, will not be discussed. Information and requirements for these types of counts can be found elsewhere (e.g., *Policy on Geometric Design of Highways and Streets*, and chapter six of the *Manual on Uniform Traffic Control Devices*).

Target Audience

The target audience for this guide is state and local agency personnel responsible for conducting traffic counts, processing count data, and generating AADT figures from the base data collected. In providing information on good practices in this regard, basic techniques and general theory are stressed. The Federal Highway Administration's *Traffic Monitoring Guide* (TMG) is recommended for those interested in a more detailed discussion of theory and practice.

Larger local agencies may already have well developed traffic counting programs. In this case, the guide may be useful for introducing new personnel to basic traffic counting techniques.

General Purpose and Objectives

There are many good reasons for counting traffic, including:

- **Production of statistics.** Many valuable statistics flow from traffic counting programs. Examples include vehicle-miles of travel figures and AADT maps, as well as vehicle usage, truck flow and commodity movement patterns.
- **Highway program design.** Highway capacity monitoring and construction scheduling depend on good traffic data. Safety monitoring programs need accurate flow information to locate unusually hazardous areas. Pavement design requires AADT and axle loading information.
- **Highway finance.** Some categories of federal funds are allocated partly on vehicle miles traveled.
- **Transportation planning.** Traffic flow and demand is essential to system monitoring and planning. The first step in planning is to establish a database that is representative of present day conditions.
- **Information for the Public.** Governmental traffic counting programs are not specifically required to collect information exclusively for use by private individuals or organizations, but the data gathered should be made available. This creates an added responsibility for producing high quality data.
- **Research and analysis.** Highway data is required for many research studies in order to reach a conclusion. However, the conclusion reached can be no better than the data upon which it is based.

Three Elements of Traffic Count Programs

In order to meet these needs, most states have implemented a count program consisting of three elements:

1. Continuous Count Element
2. Coverage Count Element
3. Special Purpose Element

Each element has its own purpose and methods, and all three elements are essential to a complete count program. The three elements are discussed below, in the level of detail appropriate to the intent of this guide.

Continuous Count Element

The continuous count element consists of a number of Permanent Traffic Recorders (PTRs), which collect data constantly throughout the year. These PTRs are distributed throughout Washington so that the variety of operational characteristics found on highways within the state is represented. By providing detailed and continuous traffic information for a representative sample of highway locations, this network of PTRs allows the following to be produced:

- **Growth rates.** Growth rates can be calculated from one or more PTR sites and then applied to other highway locations with similar geographic and operational characteristics.
- **Seasonal and day of week variation information.** Traffic streams vary in relation to both day of week and time of year. However, short duration counts, as their name implies, are restricted to collecting data for limited periods that are always less than an entire year and often less than a full week. Because of this, the average daily traffic volume from a short duration count will generally fail to accurately reflect the AADT of the location where the count was conducted. However, due to their continuous operation, PTRs record data that represent the variation of traffic streams in relation to day of week and time of year. This information can be used to calculate mathematical factors for converting short duration count data to annualized figures.
- **Axle correction factors.** Many short duration counts are restricted to simply recording the number of axle passages. Because not all vehicles are limited to two axles, merely counting all axle passages and then dividing by two cannot produce an accurate vehicle volume count. Axle correction factors, representing the ratio of vehicles to axles, must therefore be computed and applied to data limited to axle volumes in order to generate reasonably accurate estimates of vehicle volumes. To this end, data from PTRs instrumented to count and classify vehicles by type and

number of axles can be used to calculate correction factors for application to short count data.

- **Analyses of traffic relationships.** Several traffic-related relationships are commonly used in the process of highway design. One is the “K” factor, which is the proportion of daily traffic occurring during the peak hour. For design purposes, the K factor is generally calculated using the thirtieth highest volume hour of the year. This factor is directly available from PTR data, and is commonly extended to other highways when site-specific information is not available. The same is true for the “T” factor, which represents the percentage of trucks in the traffic stream.
- **Estimates of truck volumes and weights.** Because PTRs are capable of classifying vehicles, they can provide factors for use in estimating total number of trucks on the state highway system. This is done in conjunction with a separate truck-weighing program, where the average weight of various truck classes is established. This program utilizes data from Weigh-In-Motion (WIM) PTRs, which are capable of weighing and classifying vehicles automatically as they travel over the site.

Appendix Two of this guide contains a map of the State Highway System showing the location of WSDOT’s PTR stations. Data from these recorders is available upon request from WSDOT’s Transportation Data Office. In addition, several reports containing summary-level PTR data may be accessed through the WSDOT homepage at:

<http://www.wsdot.wa.gov/mapsdata/tdo/>

Coverage Count Element

The coverage count element represents the main focus of this guide. It is primarily composed of short duration counts from which AADTs have been derived through the application of appropriate seasonal, day of week, and axle correction factors. The purpose of this element is to ensure that adequate traffic data is collected to fulfill federal reporting requirements and meet point-specific and area-wide traffic information needs.

The AADT information produced through this element has a number of applications, including use in the calculation of:

- exposure rates as part of safety analyses,
- vehicle loadings as part of pavement design,
- vehicle use as part of revenue forecasts, and
- congestion rates as part of transportation system performance monitoring.

When traffic volume data from coverage counts is maintained at levels of aggregation below that of a daily total, such as by hour and direction, the data has additional uses such as:

- traffic signal timing,
- air quality analysis,
- noise analysis,
- planning studies, and
- planning the timing of maintenance and construction activities.

The adequacy of this element in meeting its intended purpose is determined by the methods used in performing counts and factoring data to generate AADTs,¹ as well as by the thoroughness of geographic coverage provided. A discussion of good practice in relation to counting and factoring techniques is provided in the following sections of this document. However, a discussion of how many counts are needed and where they should be conducted in order to attain adequate geographic coverage is beyond the scope of this document. Readers are directed to the TMG, which provides a detailed treatment of this topic.

Special Purpose Element

The special purpose element is inclusive of counts conducted to increase geographic coverage over and above that provided by the coverage count element, as well as those performed to obtain traffic information for specific projects. This element includes counts for traffic signal warrants or design, interchange design, special studies of an

¹ Another important aspect of the coverage count element is the collection and maintenance of vehicle classification and truck weight information. However, these items are beyond the scope of this publication. Readers are encouraged to reference the TMG for a discussion of this topic.

environmental nature, or counts specific to a planned development or industrial facility. Counts performed for these purposes must be designed to accommodate the needs of each individual project, and will not be discussed in detail in this guide. However, if an accurate AADT can be generated from a special purpose count, then it should be included with the pool of coverage count information.

Temporal Factors Entering Into Short Count Accuracy

The primary purpose of a coverage count is to collect traffic data that can be used in the computation of an AADT for the section of roadway where the count was performed. However, due to resource constraints, traffic counting programs usually conduct the majority of coverage counts with portable equipment left in place for short durations, and collect data for each count location on a relatively infrequent basis. This limitation on the duration and frequency of data collection becomes a matter of concern because traffic streams vary over time. As a result, the average daily traffic volume recorded during the course of a short duration count will usually fail to reflect AADT accurately.

The following discussion addresses the types of temporal variation inherent to traffic streams, as well as methods for addressing this issue within a traffic counting program so that accurate AADT figures are produced.

Rate of Growth

Rate of traffic growth is one important temporal factor that affects the accuracy of AADTs derived from short duration count data. If traffic is growing at an average annual rate of five percent, and a count is three years old, the age of the count will likely contribute to an error of approximately 15%. Since it is not economical to collect traffic data at every count location every year, it has become common practice to update AADTs through the application of a growth factor.

Traffic growth does not occur evenly across all segments of a highway system. Economically depressed areas may exhibit slower growth than surrounding areas, or even experience a decrease in traffic. As a general rule, higher functional classes of roadway (i.e., interstates and principal arterials) exhibit the highest AADT growth rates, while collectors and local streets exhibit the lowest. Traffic growth is normally higher in urban areas than in rural areas, and is often particularly high near urban growth boundaries. Growth on higher classification arterials will generally be relatively steady, while growth

on lower classes, such as collector highways, will tend to vary more in relation to local conditions.

The best source of annual growth rates for application to individual counts is the annual growth rate of count information on similar facilities in the area. When calculating growth rates in this fashion, care must be taken to ensure that enough observations are included to average out the random inaccuracies that are always present in individual counts.

Appendix Five provides annual growth rates for ten broad categories of roadway on the state highway system. These growth rates represent averages, and may be used when better information is unavailable.

Day of Week Variation

Another systematic way in which traffic streams vary is in relation to the different days of the week. The characteristics of weekend and weekday traffic flows are generally different, with extreme changes being observable on some roadways. This is illustrated by the graph on the following page, which displays daily traffic volume as a percentage of weekly average daily traffic for four typical weekly traffic patterns found on the state highway system.

Pattern 1 is reflective of many urban and rural highway locations that display a Friday traffic volume peak and a Sunday low. Pattern 2 represents a large number of other rural locations where weekend traffic is slightly higher than average due to a modest weekend recreational travel influence. Pattern 3 reflects many other urban locations where job-related weekday traffic is a particularly large component of total weekly volume, resulting in Saturday and Sunday having distinctly low traffic volumes in relation to other days of the week. Finally, Pattern 4 characterizes mountain passes and other locations that are significantly influenced by recreational travel, resulting in a large proportion of weekly traffic occurring on Friday through Sunday.

Typical Weekly Variation of Traffic Volumes Daily Traffic as Percentage of Weekly Average Daily Traffic

As suggested by the graph, if counts are conducted for less than one full week then day of week variations will often result in count data failing to accurately represent weekly average daily traffic. This issue must be addressed if reasonable estimates of AADT are to be produced from short count data. One method of doing so is to ensure that all coverage counts include at least one full week's data. However, this is often precluded due to portable equipment limitations, costs, and the increased likelihood of vandalism associated with longer counts. The alternate method is to multiply the average daily traffic figure from the count by a factor representing the ratio of average daily traffic for the week over the average daily traffic for the days of the week covered by the count. In mathematical terms the factor is expressed as:

$WF = \text{average daily traffic for the week} / \text{average daily traffic for the days counted}$

Where WF = day of week factor

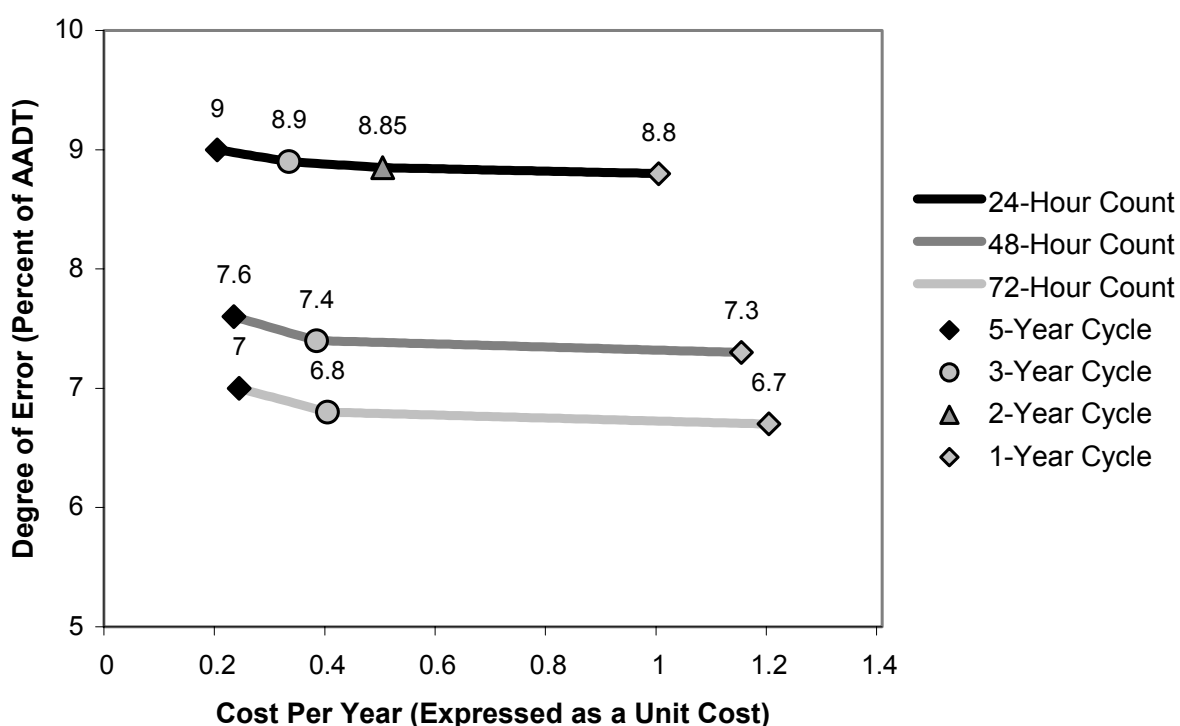

In practice however, the average daily traffic for the week will be unknown for the short count location where day of week factoring is required. As a result, day of week factors will need to be calculated for other locations (generally those with PTRs) and then applied to short counts conducted on roadway segments with similar characteristics. To reduce personnel time required to calculate and apply these factors, traffic counting programs are encouraged to standardize the days of the week that coverage counts are performed. In addition, because the day of week variation at a short count location will never precisely mirror the day of week variation of the location where factors are actually derived from, local programs are also encouraged to conduct coverage counts for at least 48 hours. Doing so will reduce the error inherent in factoring counts based on the day of week pattern found at other, albeit similar, locations. Similarly, coverage counts of less than one full week should not include data from noon on Friday through midnight on Sunday, as weekend traffic is usually more randomly variable than weekday traffic, and therefore less appropriate for factoring.

Random Variations

Traffic also varies due to less consistent influences, such as weather conditions, large sales at shopping malls, public events, or acts of God like the 1980 eruption of Mount St. Helens. The practitioner should avoid counting when it is known that normal conditions will not prevail for such reasons. For example, counters should not be set on a fairgrounds road while the county fair is in progress or near a shopping mall the day after Thanksgiving, as doing so would lead to biased representations of average yearly conditions. However, factors that may result in traffic being atypical cannot always be identified when a counter is set. As with the systematic variability of traffic in relation to day of week, local agencies should address this issue by establishing minimum count durations that achieve desired levels of precision in relation to average daily traffic volumes. A discussion of considerations pertinent to the determination of minimum count durations is provided below.

Data Accuracy Related to Count Cost, Duration and Cycle

The TMG recommends that coverage counts be 48 hours in duration and repeated every third year, with growth factors being applied in the intervening two years. This recommendation is the result of cost versus accuracy studies, and is put forth as the most effective compromise between the goal of maximizing data validity and the constraints of cost and equipment limitations. The figure below is based on research cited in support of this recommendation.² It shows the relationship found between count duration, count cycle, degree of error, and relative cost of the count program. As can be seen, as count duration and frequency are increased, program cost rises while the level of inaccuracy in AADT estimation is reduced.

The actual design of a local agency's count program depends on local needs and available resources. However, as noted above, limiting count durations to less than 48 hours should be avoided. Count periods of less than two full days increase the degree to which

² Source data for the figure are from Hallenbeck, M. E., and Bowman, L. A. (1984). *Development of a Statewide Traffic Counting Program Based on the Highway Performance Monitoring System*. Federal Highway Administration, United States Department of Transportation.

day of week and random variations result in counts failing to reflect average traffic volumes, but do not result in significant cost savings as the time required to set up and take down equipment is essentially the same regardless of count duration. Collecting multiple days of data also results in a better statistical sample for quality assurance purposes, allowing staff to compare data from similar hours of different days and identify improper equipment functioning or atypical traffic patterns from events such as accidents or other unusual circumstances.

WSDOT conducts its own coverage count program with a three-year count cycle. It has also established the policy that, whenever possible, short duration mechanical counts will be conducted continuously from noon on Monday to noon on Friday, excluding days impacted by holiday traffic, with equipment checked in the field each day for proper functioning. The goal is to capture 72 hours of valid weekday data, with 48 hours considered a minimum. Although counting over entire weeklong periods would theoretically result in average daily traffic figures that were not influenced by day of week variation, consistently performing such counts is effectively precluded by equipment limitations and other reasons noted above. As these considerations necessitate a standard count duration of less than one full week, the period from noon on Monday to noon on Friday was chosen since it is characterized by relatively consistent traffic volume patterns. Because of this, reasonably accurate average weekday traffic volumes can usually be produced even if only 48 hours of data is collected. These average volumes are then factored to compensate for the bias introduced through the exclusion of weekend data.

Seasonal Variations

The seasons of the year have a systematic effect on traffic flow. Traffic is typically depressed below average in the winter months, and elevated above average in the summer. Mid-August is generally the time of peak travel, and mid-January is commonly near the lowest period of flow. Some locations have a harvest influence in early Autumn.

The graph below displays Monthly Average Daily Traffic (MADT) as a percentage of AADT for three typical seasonal traffic patterns found on the state highway system. Pattern 1 reflects the normally modest seasonal curve of urban and urbanized areas. Pattern 2, with a stronger seasonal curve, reflects non-urbanized rural areas lacking a significant recreational traffic influence. Pattern 3 reflects rural central mountain locations heavily affected by summer recreational travel.

**Typical Seasonal Variation of Traffic Volumes
MADT as Percentage of AADT**

This graph illustrates the need to mathematically adjust short duration count data in relation to seasonal variation if the data is to provide an estimate of AADT that is not strongly influenced by the time of year the source count was conducted. This requires multiplying the weekly average daily traffic figure from a count by a factor representing the ratio of AADT over the weekly average daily traffic of the period covered by the count. In mathematical terms the factor is expressed as:

$$SF = AADT / \text{weekly average daily traffic}$$

Where SF = seasonal factor

As with day of week factors, the numerator of this fraction will be unknown for the short count location where factoring is required. Therefore seasonal factors will need to be calculated for those locations where data have been collected over an entire year and then applied to short counts conducted on roadway segments with similar characteristics.

It is a common practice to calculate seasonal factors for each month of the year and then apply the factor for a given month to short counts conducted within that month. In this case, the factor is calculated as follows:

$$SF = AADT / (\text{total monthly traffic} / \text{number of days in the month})$$

Because traffic volumes do change over the course of a month, seasonal factors calculated in this fashion are somewhat less precise than week-specific factors. However, monthly seasonal factors do have several advantages, including the fact that it is less time consuming to calculate and apply them than week-specific factors.

Axle Correction

Short duration counts often do not count vehicles, but are restricted to a tally of axle passages. Because of this, factors representing the ratio of vehicles to axles must be computed and applied to data limited to axle information in order to generate reasonably accurate estimates of vehicle volume.

The source data for computation of an axle correction factor comes from classification counts that capture both the number of vehicles (units) and the number of axles passing a count location. The process of computing an axle correction factor generally begins with the division of the total number of axles counted by two, in order to arrive at the “two-axle equivalent” volume. The next step is to divide the total number of vehicles counted during the same period by the total number of two-axle equivalents. This factor can then be used as a multiplier that, when applied to a two-axle equivalent volume collected at a location with similar characteristics, will produce a relatively accurate estimate of unit volume.

A simple example of the computation of an axle correction factor is shown below.

100	cars at	2 axles each =	200 axles
10	trucks at	3 axles each =	30 axles
5	trucks at	5 axles each =	25 axles
<hr/>			
115	vehicles with		255 axles

Two-axle equivalent volume = $255 \text{ axles} / 2 = 127.5$

Axle correction factor = $115 \text{ vehicles} / 127.5 \text{ two-axle equivalents} = .90$

Axle correction factor (ACF) = .90

The axle correction factor calculated above is fairly typical of many urban areas around industrial locations or rural areas of light to medium trucking activity. This factor is not however representative of locations where large truck traffic represents other than a moderate proportion of the traffic stream. For example, some sections of rural interstate carry high percentages of five axle and larger trucks, resulting in factors of .70 or less.

Axle correction can never be ignored when counting traffic by number of axle passages. Although in urban areas away from arterials the factor can approach 1.00, and the impact of applying a factor may be insignificant, each count location should be evaluated individually before the decision to forgo the application of an axle correction factor is made.

Appendix Three contains a table of axle correction factors by functional class of highway. These may be used when better information is not available. However, factors generated from local data should be considered of superior validity if they are from a representative sample and not skewed by special events such as harvest hauling or the presence of construction vehicles making many round trips over the same section of roadway.

Factoring Short Count Data to an AADT

As discussed, if short duration counts are to produce accurate estimations of AADT then factors must be applied to compensate for temporal variations in the traffic stream and the limitations of count equipment. Annual Average Daily Traffic should therefore be computed from short duration count data as follows:

$$\text{Estimated AADT} = \text{SF} * \text{WF} * (\text{ACF} * \text{ADT})$$

Where: SF = seasonal factor

WF = day of week factor

ACF = axle correction factor

ADT = average daily traffic from short count

If ADT is expressed in terms of unit volume as opposed to two-axle equivalent volume, then ACF is removed from the computation. If a count is inclusive of all days of the week, then WF is removed from the calculation.

To compensate for both seasonal and day of week variation, WSDOT uses data from PTRs to obtain monthly average weekday traffic to annual average daily traffic conversion factors. Each factor represents the AADT recorded by a PTR divided by the average weekday traffic (AWDT) of that PTR for a given month. These are applied to average weekday traffic volumes from short duration counts through the following formula:

$$\text{Estimated AADT} = \text{SWF} * (\text{ACF} * \text{AWDT})$$

Where: SWF = combined seasonal and day of week factor

ACF = axle correction factor

AWDT = average weekday traffic from short count

Again, ACF is removed from the equation if AWDT is expressed in terms of unit volume as opposed to two-axle equivalent volume.

Appendix Four provides average AWDT to AADT conversion factors produced from groups of PTRs with similar seasonal traffic volume trends and definable commonalities in relation to functional classification of roadway, geographic area and/or traffic features. These may be used by local agencies when factors specific to the local area are unavailable. However, it is important to note that seasonal variations come in a wide variety of patterns. Routes used almost exclusively for warm-weather recreational travel will display an even greater summer peak than presented by Pattern 3 in the graph above. A route that is strongly influenced by winter recreational activity, such as one leading to a ski resort, can actually display peak periods in the winter months. Judgment and thought should be exercised in the application of seasonal factors to ensure that the characteristics of the roadway where a count to be factored was conducted match the defining features of the factor group being used.

Short Count Equipment

The market for quality traffic data collection equipment has resulted in a number of vendors that have developed various traffic counters and an array of accompanying sensors. This allows professionals responsible for the administration of traffic counting programs to determine what their data needs are and purchase accordingly. Traffic counters today will collect volume and speed data, and are often capable of recording vehicle classification as well. Several manufactures provide portable traffic counters that will also monitor and record truck wheel, axle, and gross vehicle weights. These systems are lightweight, portable slow speed and static truck weighing scales that can be transported in the trunk of a car or the back of a truck.

Of course, in deciding upon what equipment to purchase, consideration should be given not only to the type of data that can be collected by a product, but also to the product's cost versus its performance, durability and ease of use. This cost-benefit analysis should take into account such issues as the type of power source the counter uses (e.g., long-term batteries, solar panels), whether or not the counter provides a visual display of the data as it is being collected, and the time required setting up the counter in the field. The following discussion provides a general overview of portable counters and sensors, as well as the types of data that can be collected with this equipment, in order to help inform the purchasing decisions of local traffic counting programs.

Types of Count Data

As noted above, there are a number of different types of data that can be collected using standard electronic traffic counting equipment. These include:

Volume. Volume data is by far the most commonly collected data type. Usually this data is collected using standard road tubes or inductive loops connected to an electronic counter. Older electronic counters store this data in programmable time increments ranging from one minute to 24 hours. In contrast, counters that employ newer technology

are capable of being programmed to store volume data on a per vehicle basis. This data can then be summarized at whatever interval is needed, using software provided by the manufacturer.

Classification. Vehicle classification data is probably the next most common type collected. The collection of this data usually requires the installation of two sensors in order for vehicle speed to be determined. Once the speed is determined, internal software can analyze the timing between axle hits to establish axle spacing and thus vehicle classification. Various classification schemes are in use. Most equipment capable of collecting classification data allow the user to define how vehicles are classified or use a classification scheme preprogrammed into the counter software.

The most familiar classification scheme consists of classifying vehicles as automobiles, single-unit trucks, double-unit trucks, or triple-unit trucks. Other schemes break these four categories into additional subdivisions, separating automobiles into smaller groupings (such as motorcycles, cars, pickups and vans) and further dividing the truck categories. The most well known of these more refined classification systems is the one employed by FHWA. This system breaks down vehicles into 13 different classes. However, since no mechanical vehicle classification equipment is perfect, many states have included an additional 14th class used for unknown vehicles. Other states have included additional classes for their own purposes, such as monitoring specific types of vehicles in which they have a special interest. A detailed description of the FHWA classification scheme is provided in Appendix Six.

Speed. The third most common type of data collected is speed data. It is used for many different types of studies, such as gasoline consumption, 85th percentile speed determination for design studies, and various types of environmental studies (including noise and air quality). Any electronic counter capable of classifying vehicles is also capable of collecting speed data. Again, two sensors are usually required to collect speed information. However, it is possible to collect generalized speed data using a single inductive loop if average vehicle length is known.

Weight. Truck weight data has gained importance as a planning tool since the advent of Weigh-In-Motion data collection equipment. The truck weight data collected by such equipment is an integral component of various nationally mandated programs, such as the Strategic Highway Research Program, that have been implemented with a primary goal of collecting pavement longevity information for use in pavement maintenance and design. Recently, significant advances in software and sensor equipment have dramatically improved the accuracy of WIM equipment. These systems are very sophisticated and currently very expensive. However, costs of these systems are expected to decrease as the technology becomes more available.

These systems are capable of tracking individual vehicles and providing classification, single and tandem axle weights, vehicle length, speed, Equivalent Single Axle Loads (ESALs), gross weight, and other user programmable items. Included software programs allow for manipulation of the data in various ways and provide standard and user defined reports.

Types of Counters Available

A number of different traffic counters are available. Most manufacturers offer various options, such as type of sensor that can be used, and various programs that will collect volume, speed, classification, weight, and gap and headway (measures of vehicle spacing) information or any desirable combination of the above traffic parameters. Basic computerized electronic counters can be purchased for around \$600, although prices increase in relation to functionality. The most expensive counters will do everything, including weigh vehicles and allow automated retrieval of field data via modem. Sensors represent an additional cost, with price depending upon the type of sensor chosen.

The following is a discussion of the traffic counters currently being used by WSDOT planning and regional staff for their collection programs.

GK Counter (Model 5000 and 6000). These counters are the main traffic data collection devices used by WSDOT planning staff. They are simple to program and use, and have many built-in programs for collecting volume, classification and speed data. Some of the more advanced units can also be programmed to track the speed, length, and axle spacings of each vehicle. Depending on the model, they will operate with road tubes, inductive loops, piezo cables, dynax cables or tape switches.

The manufacturer of these counters went out of business in the 1990s and since that time the counters have been maintained with limited parts. WSDOT is in the process of replacing their inventory of these counters as funding allows.

Diamond Traffic Products Counters (Unicorn, Pegasus and Apollo). The Unicorn and Pegasus counters have recently been tested by WSDOT planning staff and purchased to replace the aging and obsolete GK counters. These counters can be programmed using an onboard keyboard and display, or by connecting a laptop or desktop personal computer. Using pneumatic tube sensors, these counters can collect volume data on up to four lanes of traffic or classification data on up to two lanes.

Diamond Traffic Products has also recently released its Apollo Counter/Classifier, which is tailored specifically for cities and counties. The counter collects data at the individual-vehicle level, requires minimal set up time in the field, and is equipped with a complete LCD display so that operators can verify the accuracy of data as it is being collected. Once per-vehicle data is downloaded, manufacturer software also allows for a variety of pre-set or user-defined reports to be generated. WSDOT planning staff will test several of these units in the near future and possibly place them into service as traffic collector/recorders based on the results of the test.

Timemark Incorporated (Delta III). Several of the WSDOT regional traffic counting programs are using the Timemark Delta III portable road tube classifiers. These counters are designed to collect per-vehicle data on multi-lane, high volume roadways. Manufacturer software allows for a variety of reports to be produced from this data.

Data Storage Units

Counters usually store data in one of two ways. Some only store data in an internal memory for later downloading to a personal computer. If this type of counter is used, it is best to provide field personnel with laptop computers so that data can be downloaded to a floppy disc in the field. More commonly however, counters are designed to write to removable data modules such as PC cards. The advantage of these is that the counter itself need not be brought into the office in order to download the data, only the data module. Counters tend to be heavy and take up a lot of space. The data module provides a lightweight and space saving solution to storing data before processing. This method of data storage also frees up the counters so that they can be immediately reused in the field if additional data modules are available. Because of this, it is a good idea to have at least two and preferably three modules per counter.

Types of Sensors

In spite of all the major advancements made in electronic technology over the past decade, the technology used to detect vehicles or axles on the highway has not significantly changed. The most reliable and commonly used detection device is still the pneumatic road tube. This and other sensor types are discussed below.

Pneumatic Road Tube (Round). Used to detect the passing of axles, this sensor is an inexpensive round rubber tube or hose that is attached to a counter. A pulse of air is initiated upon wheel contact, which activates a solid-state air switch within the counter housing causing an electrical current to be registered as a single axle. Usually, two activations are recorded as a single two-axle equivalent unit.

These tubes are most efficient when used to count traffic traveling at moderate to high speeds. Their major drawback is that vehicles traveling under 25 miles per hour may not have an energy level sufficient to cause detection by most counters. As a result, they sometimes perform poorly during stop and go traffic conditions. Field personnel must

take this limitation into consideration when determining the proper location for placing pneumatic tubes.

Pneumatic Road Tubes (D). This sensor is similar to the round pneumatic tube except that it is shaped like the letter D or a half circle. This shape is intended to reduce the tendency of tubes to roll or drift forward as a vehicle passes over them, and therefore produce a more accurate count than would be achieved with round tubes. The drawback of these tubes is that they are thicker than the round type, resulting in weaker air pulses at low traffic speeds, and therefore less accurate counts under such conditions. For this reason, WSDOT planning staff no longer use D tubes, but instead employ round tubes adhered to the roadway using bituthene tape in order to control drift.

Inductive Loops . Inductive loops are used to detect the passing of vehicles. They have an advantage over road tubes in that they allow for counting at slower speeds and more accurately count volume at higher traffic densities. Their major limitation is their relatively high cost. Non-reusable portable loops are available for purchase off the shelf for around \$200, although reusable inductive loops can easily be constructed with \$30 to \$40 in supplies.

Dynax Cable. Dynax cable is best suited for use at permanent volume or classification counting installations, but portable units are also available. Their major limitation is that they are relatively expensive at around \$300 each.

Piezo Cable. Piezo cables are axle sensing devices that utilize the piezo electric phenomena to sense vehicles. When a piezo cable is compressed, it generates a current internally. The voltage of this current is used to register the passing of a vehicle axle. On higher grade cables, the magnitude of this voltage can be measured electronically to determine the weight of the passing axle. Less sophisticated electronics can be applied to piezo cables to measure speeds, count volumes, and classify vehicles. The price of this sensor is high. Cables of a grade capable of weighing vehicles in motion are currently priced around \$700, although portable cables are generally not weight grade and are used

only to classify or count vehicles. Prices for these non-weight grade sensor cables start at around \$250 per unit. If classification or speed data is desired, two cables will be necessary for each lane.

Tape Switch. This sensor is a pressure sensitive device containing a conductive pair of wires separated by a compressible material. When hit by a vehicle tire, the tape compresses bringing the two conductors in contact with each other and transmitting a current that is interpreted as an axle hit by the traffic counter. The price is around sixty dollars for an eight-foot length of tape. They are most useful for counting volumes at locations where road tubes cannot be placed or on structures where placement of inductive loops is not feasible.

Magnetometer. Magnetometers are not commonly used in traffic counting, but they do provide certain advantages over other types of sensors under certain conditions. Magnetometers are most suitable for counting vehicles on metal bridges. Since they measure disturbances in the earth's magnetic field, they are unaffected by the metallic elements in bridge structures. Unlike inductive loops, magnetometers are not affected by the metal in reinforced concrete or bridge structures. The difficulty is in their installation. Access may be difficult. However, magnetometers do not have to be embedded in the pavement. They can simply be attached externally to the underside of the concrete highway slab on structures and connected to the counting unit.

Trends in New Counting Equipment

Trends in the development of traffic counting equipment seem to be in the direction of counters, which will do more things with higher levels of accuracy. These new counters will keep track of individual axles; time stamping each axle and storing this data in memory. Data will be loaded to a personal computer and software applied to the individual axle data. Reports pertaining to volume, speeds, classification or any combination of these can then be developed using software programs. It is likely that these software programs will have built in algorithms that will automatically modify the data processing methodology based on traffic conditions that occurred during each count.

For example, if an accident occurred during the count, traffic conditions would be different after the accident occurred. These algorithms should be able to sense these changes in the collected data and adjust the headway, gap or other parameters to provide the most accurate estimate of the traffic volumes.

Tips on Setting Portable Counters with Road Tubes

When setting counters with pneumatic tubes, one must take great care to place them in the proper location. Tubes should be set an adequate distance from traffic signals or stop signs, as they do not function well in very slow or stop and go traffic. In addition, areas with numerous driveways should be avoided. Traffic turning out of a driveway will cross nearby road tubes at an angle, often resulting in four individual axle hits on the tube by a single two-axle vehicle.

The total length of a road tube should be no less than 30 feet and no greater than 60 feet, with optimal performance achieved from tubes of approximately 50 feet. If a tube is too short, inaccurate counts can result due to reflecting air pulses from the far end of the tube. If a tube is too long, vehicles impacting near the end of the tube may not register due to a weak air pulse.

To set a counter with a pneumatic tube sensor, first chain and lock the counter to a signpost, telephone pole or other fixed object on the shoulder of the road in order to prevent theft. Then lay the tube across the lanes to be counted. Fasten the far end of the tube to the surface using one-eighth inch nylon cord tied around the tube and attached to either 10-inch spikes driven into the shoulder or PK nails driven into the pavement. In a similar fashion, attach the tube to the shoulder of the roadway near the counter after stretching the tube about six inches in order to take out the slack. (Note that the tube should not be stretched too tightly as this will cut off the air pulse to the counter.) In attaching the tube at these two points, care should be taken to ensure that it is set at either a 90-degree angle to the traffic or, if the tube is collecting data for only one direction of travel, angled slightly into the oncoming traffic. At this point the tube can be attached to the counter and the equipment checked for accurate functioning.

Road tubes require periodic maintenance. The interior of the tube must be kept clean and free of water and dirt to ensure proper operation and prevent failure of the counter's air switch. The best method of cleaning is by passing compressed air through the tube.

Maintaining Accuracy of the Equipment

Properly functioning equipment is essential to the accuracy necessary for high quality traffic data. All traffic counting and classifying equipment should be tested for accurate functioning when it is first purchased. The equipment should also be inspected regularly during each field setting. Any time a major malfunction or accuracy problem occurs, or when the collected data appears to be suspicious, the equipment should be examined and repaired or replaced. In addition, the FHWA recommends that each counter be rigorously retested every three years.

The results of all equipment testing should be documented and placed in files for later retrieval and comparison with future tests.

Testing New Equipment

It is always best to have the manufacturer provide a demonstration of their merchandise and then perform some independent tests to determine the dependability of the equipment before purchasing. Testing should include getting the data in a format that will interface with your system or software.

The initial acceptance test of short duration count equipment should be rigorous. The type of test to be conducted depends on the capabilities of the new counter. If the counter is capable of vehicle classification, acceptance testing should be based at minimum on the FHWA's 13-bin classification scheme. If the counter is only capable of measuring volumes, tests should be based on either two-axle equivalent volumes (in the case of axle detection equipment such as air tubes) or unit volumes (in the case of vehicle presence detection equipment such as inductive loops). The FHWA suggests that counters collect volume data accurate to within 10%, and equipment capable of vehicle classification

should classify 90% of all vehicles accurately.

Usually, new equipment is purchased under a set of performance specifications. In this case, tests should be designed to ensure that the equipment meets these specifications. Accuracy testing of new counting/classifying equipment should be carried out per the procedures set forth in the original Request for Proposal (RFP) or specifications. If acceptance testing specifications are not included in the RFP, then one of the following two methods should be used:

- The preferred method is to check the accuracy by comparing the results of at least one manual count taken at the same time the new counter is in operation. The manual count should be taken for at least four hours on a roadway where the traffic volume is high enough to collect an adequate sample (at least 100 trucks). If the equipment being tested cannot classify, only a manual volume count will be taken. If the equipment is capable of classifying, a manual classification count will provide the basis for comparison.
- The alternate method is to check the accuracy by comparing the results of at least one mechanical count against the new counter. The count period should be for a minimum duration of four hours. The accuracy of the mechanical counter used to make the comparison should be known and well documented. If the new counter is capable of classifying, then the mechanical count will be a classification count.

Continuous Field Check

Each time a counter is set, it should be checked for proper operation and accuracy. This may be accomplished by conducting a short manual count and comparing the results to those given by the mechanical counter. This count should last for five minutes or the passing of 100 vehicles, whichever comes first. If the counter is set for classification, comparisons should be based on a manual classification count. If the counter is set to record volume only, comparisons should be based on either two-axle equivalent volumes (in the case of axle detection equipment) or unit volumes (in the case of vehicle presence

detection equipment).

For as long as the counter is set out at the site, every time the counter is field checked an additional short manual count should be made and the results again recorded. If at any time the accuracy of the counter is suspect, the sensors should first be checked. If these are not operating properly, they must be replaced. Then the manual count check can be continued until it is determined whether or not the counter is functioning properly. If the counter is found to be malfunctioning, it must be replaced immediately and the problem documented. The malfunctioning counter can then be repaired.

Three Year Cycle Testing

All counting equipment should be rigorously retested once every three years, with one third of all counters in current use tested each year. This testing should be performed and documented using the procedures described above under Testing New Equipment.

A schedule for retesting should be developed and maintained. If a piece of equipment has been tested and/or repaired for other purposes within the last three years, and is known to be functioning properly, retesting can be delayed until a three year period has elapsed.

Documentation and Retention of Test Results

All testing of equipment, and any problems discovered, should be documented for later review and comparison with other test results or collected data. It is suggested that three types of documentation be maintained:

1. A file containing data from the initial acceptance testing of equipment, the three-year cycle testing, and other testing due to the detection of operational problems. Information to be filed includes data from the counter, data from manual counts conducted for comparison, and the results of those comparisons.
2. A “counter problem record book”, where information regarding counter malfunctions and other problems is documented.

3. Field sheets that record information from the continuous field checks and other count-specific information needed by office personnel responsible for processing count data. Each sheet should be stored with a copy of the count data and other pertinent information related to the traffic count.

APPENDICES

Adjusted Count

A base traffic count that has been adjusted for axle, seasonal, and/or weekday factors.

Annual Average Daily Traffic (AADT)

Average daily traffic over the course of one calendar year.

Automatic Traffic Recorder (ATR)

A device that records the continuous passage of vehicles across a section of road.

Average Daily Traffic (ADT)

The total traffic volume during a given period (more than a day, and less than a year) divided by the number of days in that time period.

Average Weekday Traffic (AWDT)

Average daily traffic representative of weekdays only. Often calculated with Friday data excluded.

Axle Correction Factor

A factor used to adjust base axle volume data in order to compensate for the incidence of vehicles in the traffic stream having more than two axles.

Base Count

A traffic count that has not been adjusted for axle factors (effect of trucks) or day of week and month of year effects.

Base Data

The unedited and unadjusted measurements of traffic volume, vehicle classification, and vehicle or axle weight.

D

The ratio of peak hour dominant directional traffic volume to total peak hour traffic volume.

Day of Week Factor

A factor used to adjust base count data in order to compensate for travel behavior fluctuations in relation to day of week.

Directional Design Hour Volume (DDHV)

A directional hourly traffic volume used in design. Usually based on an estimated design year ADT and factored by the estimated 30th highest hourly volume and a directionality ratio.

K

The ratio of peak hour traffic to annual average daily traffic. For design, usually calculated with peak hour traffic being represented by the 30th highest hourly volume of the year.

Monthly Average Daily Traffic (MADT)

The average daily traffic over the course of one month.

Permanent Traffic Recorder (PTR)

An automatic traffic recorder that is permanently installed at a specific location.

Seasonal Factor

A factor used to adjust base count data in order to compensate for travel behavior fluctuations in relation to time of year.

T

Percentage of truck traffic.

Truck

Any vehicle with six or more tires.

Two-axle Equivalent

Traffic volume represented as the number of axle passages divided by two.

Appendix Two

WSDOT Permanent Traffic Recorders

The locations of all of WSDOT's Permanent Traffic Recorders are listed on the following pages. Statewide and Puget Sound area maps displaying these locations are also included. Upon request, data from any of these recorders may be obtained from the Department's Transportation Data Office.

Permanent Traffic Recorder

Site names beginning with “R0” are displayed on the following maps without these characters. For example, R087 is shown simply as “87”.

Axle correction factors can be derived from classification counts that provide both the number of vehicles (units) and the number of axles passing the count site. The factor is calculated by dividing the total number of vehicles by the total number of two-axle equivalents (i.e., the number of axles divided by two). If the local agency has access to vehicle classification counts within its jurisdiction, these should be used to calculate axle correction factors. Two-axle equivalent volume data should be adjusted to estimated vehicle volume data through the application of an axle correction factor derived from one or more counts conducted nearby or at a location with similar characteristics. If an appropriate factor is unavailable, one may be used from the table below, which provides statewide average daily axle correction factors by functional class of highway.

Average Axle Correction Factors by Functional Class of Highway
(Source Data From 2000 Through 2002)

<u>Code</u>	<u>Description</u>	<u>Factor</u>
01	Interstate, Rural	0.84
02	Principal Arterial, Rural	0.92
06	Minor Arterial, Rural	0.91
07	Major Collector, Rural	0.93
08	Minor Collector, Rural	N/A
09	Local, Rural	N/A
11	Interstate, Urban	0.93
12	Other Freeways and Expressways, Urban	0.96
14	Other Principal Arterial, Urban ³	0.96
16	Minor Arterial, Urban	0.95
17	Collector, Urban	0.96
19	Local, Urban	N/A

³ Data from functional classes 12 and 14 are combined to generate the factor provided for each.

If a count location can be matched to a functional class for which the table provides a factor, that value should be used. Counts conducted on a functional class 08 or 09 highway should be factored using the value closest to 1.00 provided for a rural functional class. Counts conducted on a functional class 19 highway should be factored using the value closest to 1.00 provided for an urban functional class. The exceptions to these guidelines are that: 1) if a count location, whether urban or rural, exists within an urbanized area as defined by the U.S. Census Bureau then an urban factor should be employed; and 2) if a count location is within a city with a population of less than 10,000, but not within an urbanized area, then a rural factor should usually be used.

Note that because the factors provided in the table above are based on both weekday and weekend source data, discretion is recommended regarding their use when a count to be factored is not representative of all days of the week. The importance of this is illustrated by the table beginning on the next page, which provides 2002 axle correction factors from WSDOT permanent traffic recorders. As can be seen, weekday and weekend factors are often significantly different. It is suggested that local agencies utilize the factor information below to supplement their counting programs whenever applicable.

2002 Axle Correction Factors From WSDOT Permanent Traffic Recorders

Weekday = Average Tues, Wed, and Thurs

Weekend = Average Fri, Sat, and Sun

WSDOT uses data from permanent traffic recorders to generate monthly average weekday traffic to annual average daily traffic conversion factors. These factors are then used to estimate AADTs based on AWDTs from short duration counts. Although the weekday data used to generate the factors comes only from Tuesdays, Wednesdays and Thursdays, the factors are generally applicable to 48-hour or longer counts conducted between noon on Monday and noon on Friday.

Whenever possible, short duration count data should be adjusted using factors from a nearby permanent traffic recorder installed at a location with similar traffic patterns. However, due to the high cost of PTR installation and maintenance, WSDOT does not have an applicable PTR for every short duration count location on the state highway system. To address this issue, average factors are produced from groups of PTRs with similar seasonal traffic volume trends and definable commonalities in relation to functional classification of roadway, geographic area and/or traffic features (such as a relatively high proportion of recreational travel). The factors from a given group can then be considered applicable to short count locations that have characteristics consistent with those that define the group.

The seasonal factor groups currently used by WSDOT are:

- GR-01: Urban Interstate
- GR-02: Urban Non-Interstate
- GR-03: Rural, Non-Recreational Interstate
- GR-04: Rural Central Mountain (Moderate Recreational Influence)
- GR-05: Rural, Non-Interstate, Non-Recreational West
- GR-06: Rural, Non-Interstate Southeast (High Summer Peak)
- GR-07: Rural, Non-Interstate, Non-Recreational Northeast
- GR-08: Rural, Non-Interstate Southeast (Commute Routes)
- GR-09: Rural Central Mountain (Strong Recreational Influence)
- GR-10: Recreational West

GR-01 and GR-02 represent urban interstate and urban non-interstate highway locations respectively. GR-03 represents rural interstate highway locations, with the exception of the section of Interstate 90 passing through the central mountain region of the state. GR-04 and GR-09 represent this central mountain region, with the latter reflective of highways with an extremely high summertime traffic volume peak due to recreational travel. GR-05 represents typical rural locations in the western part of the state, while GR-10 reflects western locations that are much more influenced by summertime recreational traffic. GR-06 represents rural locations in the southeast of the state strongly influenced by seasonal agriculture-related traffic, while GR-08 represents rural southeastern locations with much less seasonal variation (such as commute routes). Finally, GR-07 represents typical rural locations in the northeast of the state.

The table below provides the 2002 monthly seasonal factors for each of these groups. To use them, multiply the AWDT from a short duration count by the pertinent group's factor for the month the count was conducted in.

2002 AWDT to AADT Conversion Factors by Group

	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
GR-01	1.04	0.98	0.98	0.95	0.93	0.91	0.92	0.90	0.93	0.95	0.98	1.01

GR-09	2.07	1.99	2.10	1.80	1.44	1.15	0.87	0.85	1.12	1.33	1.78	1.81
GR-10	1.54	1.36	1.36	1.13	1.11	0.95	0.79	0.73	0.91	1.13	1.28	1.42

Under ideal circumstances, seasonal factors that are specific to the locality a short count was conducted in should be employed. However, for most local agencies these will not be available. If so, seasonal factors calculated for the general area in which the agency is located should be used. (Seasonal factors from individual WSDOT PTR sites are published within the Department's *Annual Traffic Report*, and may be useful in generating these area-specific factors.) If no localized factors are available, those provided in the table above can be utilized, although the following guidelines for their use are suggested. Group GR-02 should be used for all count locations within the boundaries of an urbanized area as defined by the U.S. Census Bureau, as well as within cities that are outside of an urbanized area but that have populations greater than 10,000. For cities of 5,000 to 10,000 people that are not in an urbanized area, the appropriate factor group will be determined by an examination of the character of local development; if the area is fairly compact and densely populated, GR-02 is likely appropriate; if not, one of the rural groups GR-05 through GR-08 is probably applicable. For all other counts (i.e., those conducted in unincorporated, non-urbanized areas or in cities with populations below 5,000 that are outside of urbanized areas), one of the groups GR-05 through GR-10 should be chosen based on geographic area and the proportion of annual traffic volume represented by traffic in the summer months.

If an estimate of the AADT for a section of highway that has not been counted in the current year is needed, and an estimate of the previous year's AADT for the section is available, a growth factor should be applied in order to estimate the current AADT. As noted in Section Three, if a data source is available that is representative of the specific locality, such as a historical set of local traffic counts, growth rates should be calculated from this data source and used. Otherwise, the growth rates given in the table below should be employed. The table provides growth rates by the same groups used for seasonal factors. The instructions given in Appendix Four regarding how to determine which seasonal factor group is most appropriate for a given count location should also be followed when deciding upon an appropriate factor group in relation to growth rates.

Growth Rate by Factor Group
(2001 to 2002)

<u>Factor Group</u>	<u>Growth Rate</u>
GR-01	1.0142
GR-02	1.0287
GR-03	1.0268
GR-04	1.0366
GR-05	1.0287
GR-06	1.0314
GR-07	1.0126
GR-08	1.0158
GR-09	1.0245
GR-10	1.0349

The following is the Federal Highway Administration's vehicle classification scheme.

1. **Motorcycles** (Optional) - All two or three-wheeled motorized vehicles. Typical vehicles in this category have saddle type seats and are steered by handlebars rather than steering wheels. This category includes motorcycles, motor scooters, mopeds, motor-powered bicycles, and three-wheel motorcycles. This vehicle type may be reported at the option of the State.
2. **Passenger Cars** - All sedans, coupes, and station wagons manufactured primarily for the purpose of carrying passengers and including those passenger cars pulling recreational or other light trailers.
3. **Other Two-Axle, Four-Tire Single Unit Vehicles** - All two-axle, four-tire vehicles, other than passenger cars. Included in this classification are pickups, panels, vans, and other vehicles such as campers, motor homes, ambulances, hearses, carryalls, and minibuses. Other two-axle, four-tire single-unit vehicles pulling recreational or other light trailers are included in this classification. *Because automatic vehicle classifiers have difficulty distinguishing class 3 from class 2, these two classes may be combined into class 2.*
4. **Buses** - All vehicles manufactured as traditional passenger-carrying buses with two axles and six tires or three or more axles. This category includes only traditional buses (including school buses) functioning as passenger-carrying vehicles. Modified buses should be considered to be a truck and should be appropriately classified.

NOTE: In reporting information on trucks the following criteria should be used:

- a. Truck tractor units traveling without a trailer will be considered single-unit trucks.
- b. A truck tractor unit pulling other such units in a "saddle mount" configuration will be considered one single-unit truck and will be defined only by the axles on the pulling unit.
- c. Vehicles are defined by the number of axles in contact with the road. Therefore, "floating" axles are counted only when in the down position.
- d. The term "trailer" includes both semi- and full trailers.

5. **Two-Axle, Six-Tire, Single-Unit Trucks** - All vehicles on a single frame including trucks, camping and recreational vehicles, motor homes, et cetera, with two axles and dual rear wheels.
6. **Three-Axle Single-Unit Trucks** - All vehicles on a single frame including trucks, camping and recreational vehicles, motor homes, et cetera, with three axles.
7. **Four or More Axle Single-Unit Trucks** - All trucks on a single frame with four or more axles.
8. **Four or Fewer Axle Single-Trailer Trucks** - All vehicles with four or fewer axles consisting of two units, one of which is a tractor or straight truck power unit.
9. **Five-Axle Single-Trailer Trucks** - All five-axle vehicles consisting of two units, one of which is a tractor or straight truck power unit.
10. **Six or More Axle Single-Trailer Trucks** - All vehicles with six or more axles consisting of two units, one of which is a tractor or straight truck power unit.
11. **Five or fewer Axle Multi-Trailer Trucks** - All vehicles with five or fewer axles consisting of three or more units, one of which is a tractor or straight truck power unit.
12. **Six-Axle Multi-Trailer Trucks** - All six-axle vehicles consisting of three or more units, one of which is a tractor or straight truck power unit.
13. **Seven or More Axle Multi-Trailer Trucks** - All vehicles with seven or more axles consisting of three or more units, one of which is a tractor or straight truck power unit.
